TECHNICAL DESCRIPTION

The ND7000 is a 4–20 mA powered microcontroller-based digital valve controller. The device contains a Local User Interface (LUI) enabling local configuration.

The powerful 32-bit microcontroller controls the valve position.

The measurements include:

- Input signal
- Valve position with contactless sensor
- Actuator pressures, 2 independent measurements
- Supply pressure
- Spool valve position
- Device temperature

Self-diagnostics guarantees that all measurements operate correctly. After connections of electric signal and pneumatic supply the micro controller (μ C) reads the input signal, position sensor (α), pressure sensors (Ps, P1, P2) and spool position sensor (SPS). A difference between input signal and position sensor (α) measurement is

detected by control algorithm inside the μ C. The μ C calculates a new value for prestage (PR) coil current based on the information from the input signal and from the sensors. The changed current to the PR changes the pilot pressure to the spool valve. Reduced pilot pressure moves the spool and the actuator pressures change accordingly. The spool opens the flow to the driving side of the double diaphragm actuator and opens the flow out from the other side of the actuator. The increasing pressure will move the diaphragm piston. The actuator and feedback shaft rotate. The position sensor (α) measures the rotation for the μ C. The μ C using control algorithm modulates the PR-current from the steady state value until the new position of the actuator, according to the input signal, is reached.

Fig. 1. Local User Interface (LUI) enables real time awareness of control parameters in the device at a glance.
